

Practical 10

CMS and AJAX

1. Create Websites using joomla and wordpress.
2. Username Suggest:
 - Create a Label and a Textbox for getting username from the user. As the user types a character, the suggestion for username should be given to the user (like Google Suggest). The list of usernames will be stored in an array. The program should match the list of names and give suggestions.
3. Using AJAX develop a web page to display a drop down list of Users. When user selects a user from the drop down, the details of selected user (Firstname, Lastname, Hometown, Job) should be listed in a table. The user details are store in the database table.
